# SECTION 3 BLOCK DIAGRAM

# SECTION 4 CIRCUIT DESCRIPTION

## 4-1 RECEIVER CIRCUITS

### 4-1-1 RF SWITCHING CIRCUIT (MAIN UNIT)

The IC-R72 has two antenna connectors. RF signals enter either the [50 Ω ANT] or [500 Ω ANT] connector.

RF signals from the [50 Ω ANT] connector pass through a low-pass filter (C49, C50, L79, L80) and then are applied to J13.

RF signals from the [500 Ω ANT] connector pass through L19 to obtain clear reception and then are applied to the low-pass filter via J13.

### 4-1-2 RF BANDPASS FILTER CIRCUIT (MAIN UNIT)

Either the signals bypass or pass through attenuator circuits. The attenuator circuits consist of 10 dB and 20 dB attenuators. The signals are attenuated at 30 dB when passing through the attenuators. This system excludes non-linear components between an antenna connector and an attenuator to prevent strong signals from causing distortion. The signals are then applied to the RF filters. The MAIN UNIT has 6 RF bandpass filters for signals above 2.0 MHz and 2 low-pass filters for signals below 2.0 MHz.

#### (1) 0.5~1.6 MHz

The signals are applied to a low-pass filter consisting of C54~C57, L21, L22. A diode is removed at the entrance of the low-pass filter. This device prevents the diode from causing distortion when receiving very strong signals. A switching diode (D22) is turned on when the "B0" line is "HIGH". The filtered signals bypass a preamplifier circuit (Q11, Q12) and then are applied to a 1st mixer circuit (Q16, Q17) via D37, D39.

#### (2) 1.6~30MHz

The signals are applied to a high-pass filter consisting of C59~C63, L24, L25. This filter suppresses strong signals below 1.6 MHz such as broadcasting stations.

The filtered signals below 2.0 MHz are applied to a low-pass filter via a switching diode (D23). The switching diodes (D23, D24) are turned ON when the "B1" line is "HIGH."

The filtered signals above 2.0 MHz are applied to one of 6 bandpass filters depending on the receive frequencies.

After passing through a bandpass or low-pass filter, the signals are applied to the preamplifier circuit (Q11, Q12).

#### (3) FILTER SWITCHING CIRCUIT

The RF bandpass filter corresponds to the BPF switching voltage (B0~B7) based on the CPU via a current amplifier (IC3). The switching voltage of the BPF entrance is higher than the BPF exit to improve multi-signal and strong signal characteristics.

### 4-1-3 PREAMPLIFIER CIRCUIT (MAIN UNIT)

The preamplifier circuit uses low-noise junction FETs (Q8, Q9 2SK125×2) to provide 10 dB gain over a wide frequency range.

When the [PREAMP] switch is turned ON, the signals from the RF filter are amplified by the preamplifier circuit (Q11, Q12). When the [PREAMP] switch is turned OFF, the signals bypass the preamplifier through D37 and D39. When the operating frequency is below 1.6 MHz, a bypass switch (Q15) is turned ON. The signals bypass the preamplifier regardless of the [PREAMP] switch.

The amplified or bypassed signals are applied to the 1st mixer circuit (Q16, Q17) via a low-pass filter. The low-pass filter attenuates at 35 MHz to suppress image frequency.

#### • RF BANDPASS AND PREAMP CIRCUITS

Fig. 1

#### 4-1-4 1ST MIXER CIRCUIT (MAIN UNIT)

The filtered signals are mixed with a 70.9515~100.4515 MHz 1st LO signal to produce a 70.45 MHz 1st IF signal at the 1st mixer circuit (Q16, Q17.)

#### 1ST IF FREQUENCY

MODE	FREQUENCY (MHz)
SSB	70.4515
CW	70.4506
AM, FM	70.4500

The 1st mixer circuit employs a balanced mixer using low-noise junction FETs (Q16, Q17 2SK125×2) to expand the dynamic range.

The 70.9515~100.4515 MHz 1st LO signal is applied to an LO amplifier (Q1) from the PLL UNIT via J1. The amplifier outputs approx. 25 dBm. The signal is applied to a low-pass filter. The low-pass filter employs a ring core inductor to prevent leakage from the 1st LO signal. The filtered signal is applied to the 1st mixer circuit.

The 1st IF signal is applied to a MCF (Monolithic Crystal Filter; F12) to suppress out-of-band signals. The filtered signal is amplified at a 1st IF amplifier (Q18) and then applied to a 2nd mixer circuit (IC1).

#### 4-1-5 IF CIRCUITS (MAIN UNIT)

The 1st IF signal is mixed with a 61.44 MHz 2nd LO signal to produce a 9 MHz 2nd IF signal at the 2nd mixer (IC1). IC1 is a DBM (Double Balanced Mixer). The 61.44 MHz 2nd LO signal is applied to the 2nd mixer from the PLL UNIT via J2.

#### 2ND IF FREQUENCY(MHz)

MODE	FREQUENCY (MHz)
SSB	9.0115
CW	9.0106
AM, FM	9.0100

#### • IF CIRCUIT

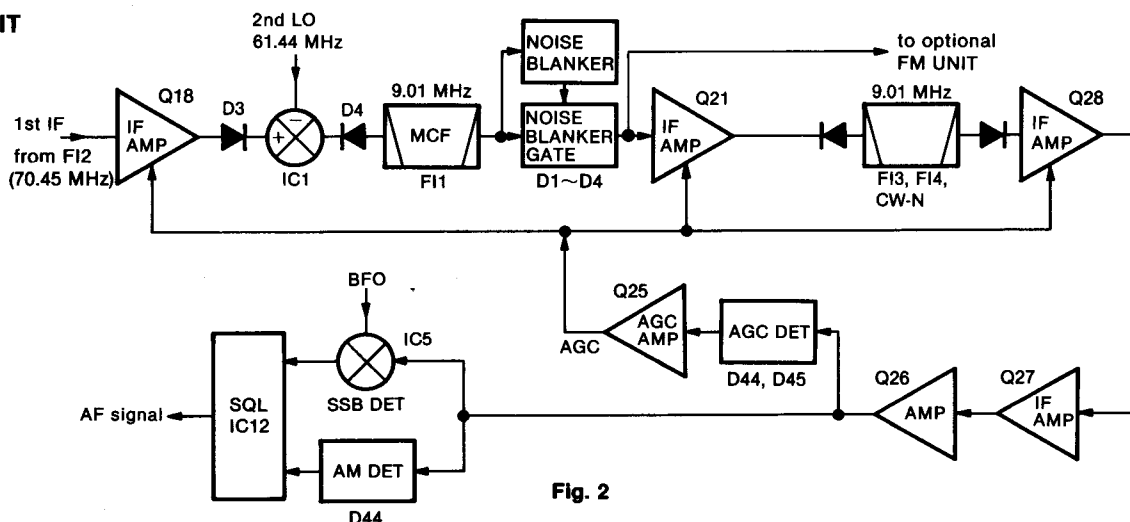

Fig. 2

The 9 MHz 2nd IF signal is applied to the MCF (F11) to suppress unwanted signals.

The filtered signal enters the noise blanker gate (D1~D4). The signal is applied to L12 to obtain clear reception and is then amplified at the 2nd IF amplifier (Q2). The amplifier outputs approx. 22 dBm. The signal passes through a loose resonator circuit (C22, L13) and then is applied either to one of the four 9 MHz filters (F13, F14, F15, or an optional CW narrow filter) or to an optional FM RECEIVE UNIT. F13 is an SSB mode filter covering the 2.3 kHz bandwidth. F14 and F15 are AM mode filters covering the 6 kHz band width. The filters are selected with mode-selecting signals (SSB, CW, AM, CW-N).

The filtered signal is amplified at the 2nd IF amplifiers (Q26~Q28) and applied to the demodulator circuits.

Dual-gate FETs are used on the 1st and 2nd IF amplifiers (Q2, Q18, Q28). The 2nd gate of Q2, Q18, and Q28 are controlled by AGC bias voltage. A rapid time constant is used for Q28 to prevent an increase in the edge distortion of the receive signal.

A thermistor (R125) is connected to the gate of Q27 to improve the temperature characteristics of the receiver gain. R123 adjusts the receiver gain.

#### 4-1-6 NOISE BLANKER CIRCUITS (MAIN UNIT)

The IC-R72 uses a noise trigger noise blanker circuit which removes pulse-type noise signals at the noise blanker gate (D1~D4).

The 2nd IF signal passes through the MCF (F11) to suppress unwanted signals. A portion of the output signal is applied to a noise amplifier circuit (Q3, IC2) and detected at a noise detector circuit (D70, D71). The detected voltage is applied to a noise blanker switch (Q6).

The threshold level of the noise blanker switch (Q6) is set at 0.6 V. When the detected voltage exceeds the threshold level, Q7 outputs a blanking signal to activate the noise blanker gate (D1~D4).

A portion of the detected voltage is applied to the noise blanker AGC circuit (Q5). The noise components are fed back to the noise amplifier (IC2). The time constant of the noise blanker AGC circuit is determined by R43, R47 and C45. This AGC circuit does not operate to detect pulse-type noise.

When the operating frequency or mode is changed, the "DNB" signal line becomes "LOW", turning Q7 ON. The noise blanker gate prevents PLL click noise.

#### 4-1-7 BFO CIRCUIT (MAIN UNIT)

A 9 MHz signal is oscillated at the BFO circuit (Q32, X1). The signal is buffer-amplified at Q33 and applied to a product detector (IC5). The BFO frequency is shifted with a mode signal using D53~D55.

In USB mode, the "USB" signal line becomes "HIGH", turning D55 ON. The frequency is then adjusted with C191 to set the USB carrier point.

In LSB and AM mode, the "LSB, AM" signal line becomes "HIGH", turning D54 ON. The frequency is then adjusted with L75 to set the LSB, AM carrier point.

In CW mode, the "CW" signal line becomes "HIGH", turning D54 ON. The frequency is then adjusted with C186 to set the CW carrier point.

#### BFO FREQUENCY IN EACH MODE

MODE	FREQUENCY (MHz)
USB	9.0130
AM-N	9.0115
LSB, AM	9.0100
CW	9.0098

#### 4-1-8 DEMODULATOR CIRCUITS (MAIN UNIT)

The demodulator circuit consists of 2 detector circuits.

A product detector (IC5) demodulates the SSB and CW signals into an AF signal. The 2nd IF signal from the IF amplifier (Q26) is mixed with the BFO signal at the product detector (IC5) to be demodulated into an AF signal. The AF signal passes through the AF input mode selector switch (IC12).

A diode detector (D46) demodulates the AM signal into an AF signal. The 2nd IF signal from the IF amplifier (Q26) is applied to C151 and detected at the diode detector (D46) to be demodulated into an AF signal. The AF signal passes through the AF input mode selector switch (IC12).

#### 4-1-9 AF INPUT MODE SELECTOR SWITCH (MAIN UNIT)

The AF input mode selector switch (IC12) consists of 4 analog switches and they are selected with a mode signal from IC9 and the squelch control signal. The AF signal is output from IC12 (pin 4).

#### IC12 AF INPUT MODE SELECTOR SWITCH

MODE	ACTIVATING PIN NUMBERS	CONTROL PIN NUMBER
USB, CW	2 → 1	13
AM	3 → 4	5
FM	10 → 11	12
ALL MODE	9 → 8	6

#### 4-1-10 AF AMPLIFIER CIRCUIT (MAIN AND FRONT UNITS)

The AF signal output is applied to the AF preamplifier circuit (Q30, Q31).

The amplified signal is applied to the [AF] control (R1) on the FRONT UNIT and passes through the 2.8 kHz cut-off active low-pass filter (Q29). The AF signal is power-amplified at IC6 to drive the speaker.

#### 4-1-11 AGC AND S-METER CIRCUITS (MAIN UNIT)

The receiver gain is determined by voltage on the AGC line (Q25, collector). When strong signals are received, the AGC circuit decreases the voltage on this line.

The 2nd IF signal is amplified at the IF amplifier (Q26). A portion of the IF signal is applied to C146 and detected at D44 and D45. The detected voltage enters the base of Q25 to control the voltage on the AGC line.

The AGC voltage is determined by R103, R104, and D43 when receiving no signal on the AGC line. R103 decreases the AGC voltage.

The fast AGC is normally used when receiving a signal in CW or AM mode, or when searching for a signal with the [MAIN DIAL]. When the [AGC] switch is pushed IN, a time constant (C142, R102) is connected to the AGC line to obtain a rapid AGC release time.

The slow AGC is normally used when receiving a signal in SSB mode. When the [AGC] switch is pushed OUT, a time constant (C141, R101) is connected in parallel with the AGC line to obtain a slow AGC release time.

The AGC function is not activated when receiving a signal in FM mode.

The AGC bias voltage is applied to the differential amplifier (IC4, pin 6) which compares the bias with the reference voltage. The resulting S-meter signal passes through the meter switching circuit (IC12) and then is applied to the [S.meter] on the front panel. The reference voltage is adjusted with R99. The inside pins 8 and 9 of IC12 are connected while receiving a signal.

The FM S-meter signal from the optional FM UNIT is applied to the squelch circuit (IC4, pin 2).

#### 4-1-12 SQUELCH CIRCUIT (MAIN UNIT)

The squelch circuit mutes the audio output when the S-meter signal is lower than the [SQUELCH] control setting level. The S-meter squelch circuit functions in any mode.

The S-meter signal from IC4 (pin 7) is applied to the comparator (IC4, pin 2) to compare with the threshold level controlled by the [SQUELCH] control. The [SQUELCH] control signal is applied to control terminals of the AF input mode selector switch (IC12). When the S-meter signal is lower than the threshold level, the comparator becomes "HIGH." The squelch gate (Q21) turns OFF to deactivate the AF input mode selector switch (IC12). This signal is applied to Q44, turning OFF the [BUSY] indicator; the signal is also applied to the [REC REMOTE] jack.

### 4-2 PLL CIRCUITS

#### 4-2-1 GENERAL DESCRIPTION

The PLL UNIT generates a 1st LO signal (70.5500~100.4530 MHz variable) and 2nd LO signal (61.44 MHz fixed) used in the MAIN UNIT. The IC-R72 uses a dual loop PLL system. A main loop PLL uses 4 VCO circuits for all HF band coverage in 512 kHz steps. A sub loop PLL uses a DDS (Direct Digital Synthesizer) system for 512 kHz coverage in 10 Hz steps. The DDS system provides rapid lockup time and high quality frequency oscillation.

#### 4-2-2 REFERENCE OSCILLATOR CIRCUIT (PLL CIRCUIT)

The reference oscillator circuit consists of Q33 and X2. A 30.72 MHz reference frequency is oscillated to produce a 2nd LO signal and PLL reference frequency.

#### 4-1-13 TUNING INDICATOR CIRCUIT (MAIN UNIT)

The tuning indicator circuit lights up the front panel in red when receiving the center of a signal in AM or FM mode.

The BFO circuit oscillates a 9.0100 MHz reference frequency to compare with the 2nd IF signal when receiving a signal in AM mode. This indicator goes on and off according to modulation. Both the BFO reference and 2nd IF signals pass through the amplifiers (Q37, Q47) and then enter the amplifiers (IC10a, IC10b) to convert the phase of a signal. IC11a is a comparator circuit which compares the phase of the BFO and 2nd IF output. IC10d is a buffer inverter circuit which stabilizes the input level of IC11b. IC11b is also a comparator which detects the phase of the BFO and 2nd IF output. The signal is applied to D66. The detected signal controls Q38. The amplifiers (Q39, Q41) drive the TUNE LED.

The tuning signal from the optional FM UNIT controls Q38 to drive the TUNE LED.

The reference frequency is buffer-amplified at Q34 and divided by 2 at IC15 to obtain the PLL reference frequency for the PLL IC (IC13).

The 30.72 MHz reference frequency is multiplied by 2 at Q36 to obtain the 2nd LO signal. The resulting 61.44 MHz signal is applied to the bandpass filter. The filtered signal is applied to the 2nd mixer on the MAIN UNIT via P4.

#### 4-2-3 MAIN LOOP (MAIN UNIT)

The main loop uses a PLL IC (IC13) which contains a programmable divider, phase detector, data shift register and data latch circuit. The VCO circuit (Q15, Q17, Q19, Q21) generates a 70.5515~100.4515 MHz signal in 512 kHz steps for the 1st LO signal. Because the sub loop produces 10 Hz steps, the PLL produces a 30 MHz frequency range in 10 Hz steps.

The 70.5515~100.4515 MHz signal is buffer-amplified at Q23. The signal is mixed with the sub loop output (fLO: 62.05~62.56199 MHz) at IC16 to produce a 8.5015~37.88951 MHz signal. An isolator (Q23) is installed to ensure that the mixer input does not affect VCO output.

The resulting signal is amplified at Q27 and then applied to the low-pass filter (L23~L25, C92, C93, C99~C103). The filtered signal is amplified at Q26 and then divided by 4 at IC14. The output signal is applied to the PLL IC (IC13).

A 512 kHz reference frequency (fREF) is applied to the PLL IC (IC13) to detect the phase of the divided signal at IC14. The phase detected signal is then output from IC13 (pin 17). The 512 kHz frequency is obtained from the reference oscillator (Q33). A 30.72 MHz reference frequency is oscillated at Q33 and then divided by 2 at IC15. The resulting signal is divided by 30 at the programmable divider section of IC13.

The phase detected signal is applied to the loop filter (Q12~Q14) to obtain PLL lock voltage. The PLL lock voltage is applied to the VCO. Thus, the VCO output (PLL output) is locked to produce stable oscillation.

The PLL oscillation frequency is obtained by the following calculation:

$$fV = fLO + NT \times fREF$$

- fV : Main loop output
- fLO : Sub loop output
- NT : Dividing ratio from the CPU
- fREF: Reference frequency (512 kHz)

• PLL CIRCUIT BLOCK DIAGRAM

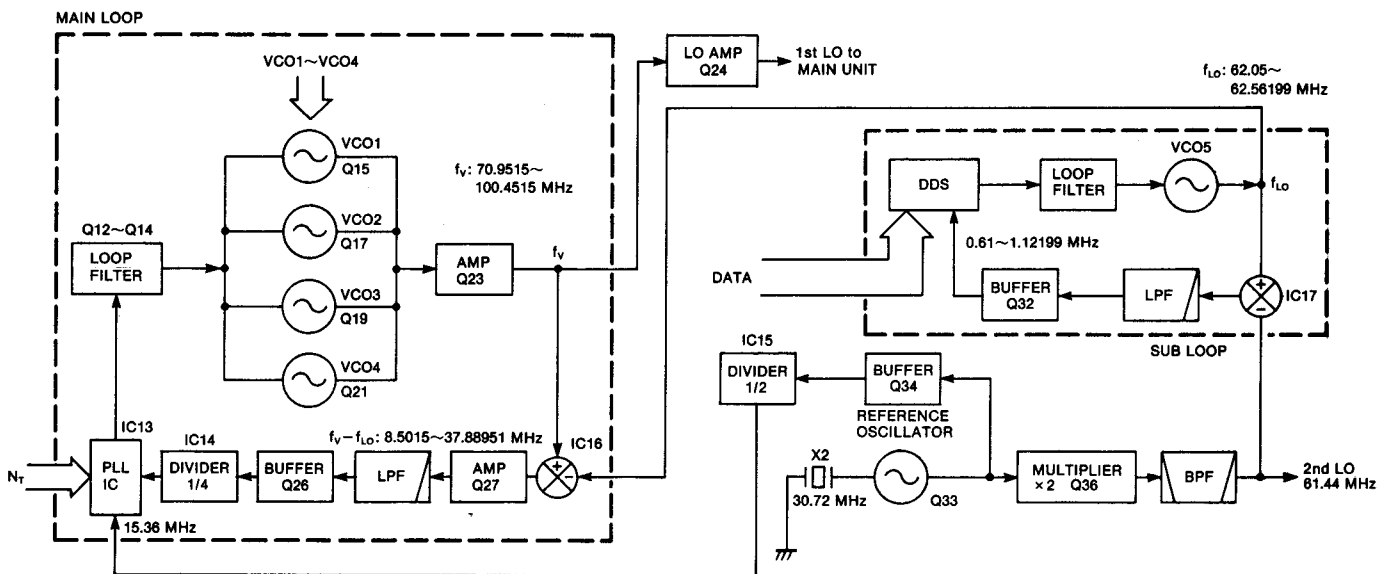

Fig. 4

4-2-4 VCO CIRCUIT (PLL UNIT)

The receiver's C/N ratio is determined by the VCO and the loop filter. 4 VCO circuits keep the noise low and reduce spurious emissions. The VCO switches (Q16, Q18, Q20 and Q22) select the operating VCO with "VCO1~VCO4" lines.

4-2-5 SUB LOOP (PLL UNIT)

The sub loop uses the DDS system that generates a 62.05~62.56119 MHz signal in 10 Hz steps.

The 62.05~62.56119 MHz signal is oscillated at VCO 5 (Q29). The signal is buffer-amplified at Q30 and then mixed with the 61.44 MHz 2nd LO signal at IC17 to produce a 0.61~1.12199 MHz signal. The resulting signal is applied to the low-pass filter and then amplified at Q32. The amplified signal is then applied to the DDS unit.

The DDS UNIT outputs pulse-type signals. The signal is applied to the loop filter (R133, R134, C114, C115, L42) to obtain a DC signal (lock voltage). The lock voltage is applied to the VCO to lock the oscillating frequency.

### (2) 8 V REGULATOR (MAIN UNIT)
